EXPERIMENT NUMBER: 4

Aim:Implement a Backpropagation algorithm to train a DNN with at least 2 hidden layers.

Objective:

To implement various training algorithms for feedforward neural networks.

Software Used :Python

Theory:

(a) Backpropagation algorithm

Backpropagation is the essence of neural network training. It is the method of fine-tuning the weights of a neural network based on the error rate obtained in the previous epoch (i.e., iteration). Proper tuning of the weights allows you to reduce error rates and make the model reliable by increasing its generalization.

Backpropagation in neural network is a short form for “backward propagation of errors.” It is a standard method of training artificial neural networks. This method helps calculate the gradient of a loss function with respect to all the weights in the network.

Two Types of Backpropagation Networks are:

- Static Back-propagation
- Recurrent Backpropagation

Static back-propagation:

It is one kind of Backpropagation network which produces a mapping of a static input for static output. It is useful to solve static classification issues like optical character recognition.

Recurrent Backpropagation:

Recurrent Back propagation in data mining is fed forward until a fixed value is achieved. After that, the error is computed and propagated backward.

The main difference between both of these methods is: that the mapping is rapid in static back-propagation while it is nonstatic in recurrent backpropagation.

Algorithm:

Step 1: Inputs X, arrive through the preconnected path.

Step 2: The input is modeled using true weights W. Weights are usually chosen randomly.

Step 3: Calculate the output of each neuron from the input layer to the hidden layer to the output layer. Step 4: Calculate the error in the output

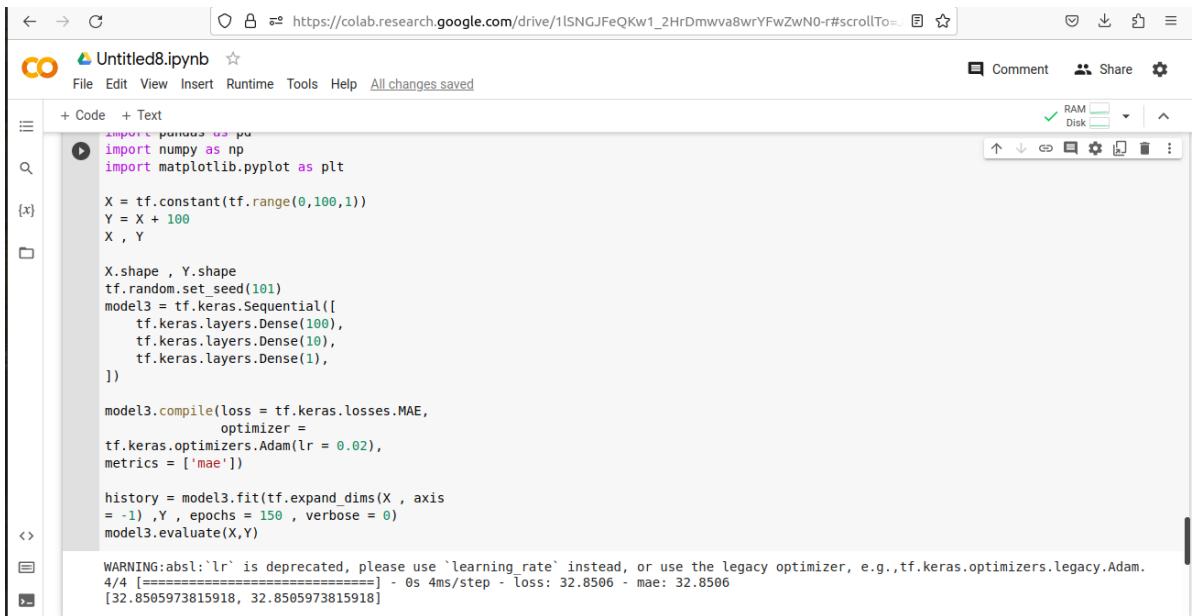

Step 5: From the output layer, go back to the hidden layer to adjust the weights to reduce the error. Step

6: Repeat the process until the desired output is achieved

Program:

```
import tensorflow as tf  
import pandas as pd  
import numpy as np  
import matplotlib.pyplot as plt  
  
X = tf.constant(tf.range(0,100,1))  
  
Y = X + 100  
  
X , Y  
  
X.shape , Y.shape  
tf.random.set_seed(101)  
model3 = tf.keras.Sequential([  
    tf.keras.layers.Dense(100),  
    tf.keras.layers.Dense(10),  
    tf.keras.layers.Dense(1),  
])  
  
model3.compile(loss = tf.keras.losses.MAE,  
                optimizer =  
                tf.keras.optimizers.Adam(lr = 0.02),  
                metrics = ['mae'])  
  
history = model3.fit(tf.expand_dims(X , axis  
= -1) ,Y , epochs = 150 , verbose = 0)  
  
model3.evaluate(X,Y)
```

Output:

The screenshot shows a Google Colab notebook titled "Untitled8.ipynb". The code cell contains the following Python script:

```
import numpy as np
import tensorflow as tf
import matplotlib.pyplot as plt

X = tf.constant(tf.range(0,100,1))
Y = X + 100
X , Y

X.shape , Y.shape
tf.random.set_seed(101)
model3 = tf.keras.Sequential([
    tf.keras.layers.Dense(100),
    tf.keras.layers.Dense(10),
    tf.keras.layers.Dense(1),
])
model3.compile(loss = tf.keras.losses.MAE,
                optimizer =
tf.keras.optimizers.Adam(lr = 0.02),
metrics = ['mae'])

history = model3.fit(tf.expand_dims(X , axis
= -1) ,Y , epochs = 150 , verbose = 0)
model3.evaluate(X,Y)

WARNING:absl:`lr` is deprecated, please use `learning_rate` instead, or use the legacy optimizer, e.g.,tf.keras.optimizers.legacy.Adam.
```

The output of the code cell shows the results of the training process, including the final loss and MAE values.

Conclusion/Outcome:

Thus we have implemented a Backpropagation algorithm to train a DNN with at least 2 hidden layers.
